

Pitches:

1) Sport Prediction App

This will be an app that allows the user to get a simple report on a specific matchup. The user will select two teams to face off, then the app will use data to determine the likelihood of either team winning, display past matchups, as well as some helpful information. If done for a single sport (e.g. soccer), two or more API's will be used for previous match data to be supplied to an algorithm. This can be applied to multiple sports as well. The database can contain information within user profiles.

2) Store Locator App

This app will allow the user to find the nearest store to them that sells the item they want. This will be narrowed down to one category of store (e.g. specific food, certain consumables). First, the user will select what kind of the item they want (flavors, price etc.). An API will be used to take that data and determine the right item. Another API will then be used to find a store for that item. The database can contain information within user profiles.
